Screen Printing vs DTF vs DTG for Shirts in Pacoima

Choosing a shirt decoration method is less about finding the single best process and more about matching the method to the order. Fabric type, artwork, quantity, color count, turnaround, and the feel of the finished print all matter. For anyone comparing DTF transfers Los Angeles options with other decoration methods, the useful question is simple: what is being printed, how many shirts are involved, and how should the final design look and feel?

Screen printing, direct to film printing, and direct to garment printing can all produce strong results, but they solve different problems. Screen printing is built around stencils and ink pushed through mesh. DTF uses a printed film, printing powder, and a heat press to place the design onto fabric. DTG prints ink directly into the garment with specialized equipment and pretreatment solution on many cotton fabrics. The right choice depends on the details of the job rather than the popularity of one method.

How each method works

Screen printing separates a design into individual color screens. Each screen blocks ink everywhere except the area meant for that color. Ink is pushed through the mesh onto the shirt, then cured so it bonds to the fabric. A simple one color design uses one screen. A full-color image requires process screens or simulated process work, which takes more setup. Because setup is part of the process, screen printing often becomes more practical as quantities rise and the same design repeats.

Direct to film printing starts with artwork printed onto transfer film using inkjet printing. The printed film is coated with printing powder, then heat is applied so the powder can become part of the transfer. The design is later placed on the garment with a heat press. This approach separates printing from the shirt itself, so transfers can be made in advance and pressed later. It is a flexible choice for mixed garment types and for designs that would be awkward to separate into screens.

View the location on Google Maps

DTG printing applies ink directly to the fabric. Many cotton garments are treated with pretreatment solution before printing, which helps the ink sit and bond as intended. The garment is then printed and cured. Since there is no screen or transfer film, DTG can reproduce detailed artwork and gradients without color separations. The trade-off is that fabric preparation and garment type have a bigger effect on the result.

Fabric and finish differences

Cotton is the common ground where all three methods can work well, though the finish differs. Screen printing usually leaves a slightly raised ink layer that is familiar on tees and uniforms. It can feel smooth or heavy depending on the ink, mesh, and design size. DTG tends to feel softer because the ink becomes part of the fabric surface rather than sitting as a thick layer. DTF creates a distinct printed layer on top of the fabric, often with a smooth, flexible hand feel when pressed correctly.

Blends, polyester, and performance fabrics can shift the decision. Screen printing may need inks chosen for the fabric to avoid issues such as dye migration or poor adhesion. DTG is most predictable on cotton and some cotton-rich garments, while blends can change color and detail. DTF is often considered when a shop needs one decoration approach across cotton, polyester, and blended garments. That flexibility can be useful for mixed orders, but the heat press settings and transfer choice still need care.

Dark garments bring another difference. Screen printing often needs an underbase so colors stay bright. DTG also relies on pretreatment and ink layers to keep detail visible. DTF transfers and gang sheets can include a white layer beneath the color, which helps designs read clearly on dark fabric. That white layer is one reason many shops use film transfers when an order includes both light and dark shirts.

Artwork and color detail

Simple logos, bold type, and flat shapes usually favor screen printing. These designs separate cleanly, repeat well, and can be printed consistently across a larger batch. If the artwork has only a few solid colors, the screen process is straightforward. Fine lines and tiny text still need careful handling, especially on textured fabric, but the method is well suited to crisp graphic shapes.

Photographic images, gradients, shadows, and full-color artwork point toward DTG or DTF. DTG prints the image directly, with print resolution shaped by the equipment and fabric. DTF prints the artwork to film first, then transfers it, so the detail is carried in the printed film. Both can avoid the labor of separating many colors, though very small details can still be lost if the artwork is low resolution or the garment surface is uneven.

There is also the matter of placement. A large back print, a left chest mark, sleeve prints, and multiple locations all change the workload. Screen printing can repeat placements efficiently once screens are set. DTF is convenient when different placements use the same artwork file or when several small designs are grouped together. DTG handles multiple placements directly, but each location adds handling and print time.

Order size and repeatability

Quantity is one of the strongest deciding factors. Screen printing has more setup at the start, then becomes efficient across repeated shirts. For larger runs with the same design, same colors, and same garment, it is often the practical choice. The more consistent the order, the more the setup works in its favor.

Small runs and mixed sizes often lean toward DTG or DTF. DTG avoids screen setup, so a single shirt or a short run can be produced without building stencils. DTF also avoids screens and adds the option of printing transfers ahead of time. For orders with many different designs, this can reduce the need to treat every name or graphic as a separate screen job.

Reorders are easier with some methods than others. Screen screens can be kept for future runs, which helps when the same design returns. Digital files used for DTG or film printing can also be stored, though fabric choice and press conditions still need to be checked again. Consistency depends on controlling the whole process, not just keeping the artwork file.

Where gang sheets fit

A gang sheet layout places multiple transfer images on one sheet of film. This is useful when an order includes several designs, names, numbers, or sizes that can be printed together. Instead of producing each transfer separately, the designs are arranged to use the film efficiently. The same idea supports small batches and mixed artwork, provided the layout leaves enough spacing for clean cutting and handling.

For shirts in Pacoima and nearby parts of Los Angeles, the practical benefit is flexibility. A local option is Custom Shirt Printing. A customer comparing methods may want to know whether one design is needed on many shirts or many designs are needed across a few shirts. That distinction often decides between screen printing and a film based approach. DTF transfers Los Angeles searches often lead to this question, because film transfers can suit short runs, varied garments, and designs with many colors.

Many shops also use DTF transfers and gang sheets when they want to press designs onto different garments as orders come together. The film can be produced before pressing, which helps with organization. A gang sheet layout still needs attention to spacing, image size, and cutting accuracy. Crowded layouts can lead to uneven edges or wasted film, so a clean arrangement matters as much as the artwork itself.

Durability and day-to-day wear

All three methods can hold up well when the right materials and settings are used. Screen printed inks are known for strong color and durability on suitable fabrics. DTG prints can be

soft and detailed, though the feel and life of the print depend on fabric, pretreatment, and curing. DTF prints form a layer on the fabric, and durability depends on correct powder application, pressing temperature, pressure, and time.

Wash care is part of the decision. Designs intended for work shirts, school clothing, or frequent washing need proper curing and compatible materials. Heat and aggressive washing can affect any print over time. A print that looks excellent on the day it is made can still change if the garment is washed hot, dried harshly, or exposed to friction. Asking how a specific print should be cared for is more useful than assuming all decorated shirts behave the same way.

Stretch is another practical factor. A solid design across the chest behaves differently from a large print over a stretchy fabric. Cracking or lifting can happen when a print layer cannot move with the garment. Screen printing inks, DTG ink layers, and DTF transfers each respond differently, so the garment and design size should be considered together.

Cost drivers without guesswork

Price depends on the shop, order size, garment, artwork, and number of print locations, so the details should be confirmed with whichever business is chosen. In general terms, screen printing cost is shaped by screens, ink colors, setup, and quantity. DTG cost is shaped by garment preparation, print time, and the number of items. DTF cost is shaped by film use, transfer production, pressing time, and layout efficiency.

This is why a design with one color on 50 identical shirts may compare very differently from 50 shirts with different names. The first case suits a repeatable screen process. The second may suit a digital or film method where each name does not require a new screen. A large photo on a dark shirt raises different questions from a small chest logo on a light tee.

Turnaround can also matter. Screen printing needs setup before production. DTG can begin from a prepared digital file once garment preparation is accounted for. DTF can separate transfer printing from pressing, which may help when multiple garment types are involved. Actual timing should be confirmed with the business handling the order, since workload and order details vary.

Choosing method by order type

For uniforms, team shirts, event tees, and branded basics with simple artwork in larger quantities, screen printing is often the straightforward match. It is especially sensible when the same design appears on many shirts and the fabric is consistent. Solid shapes and limited colors help keep the process clean.

For detailed artwork, short runs, or shirts that vary by name and number, DTG or DTF is usually easier to justify. DTG is a natural fit for cotton garments when a soft finish and fine detail are priorities. DTF is useful when the order includes blended fabrics, dark garments, or several designs that can be arranged on one film sheet.

For a mixed order, it helps to separate the decision by garment and design. A shop may use one method for a simple front logo and another for a detailed back image. That approach can be sensible when the order contains both repeatable and variable elements. The key is to compare the finished feel, fabric compatibility, setup, and production flow before committing.

Questions to ask before placing the order

A clear brief prevents most confusion. Include the garment fabric, shirt colors, artwork file, print size, placement, quantity, and any variation by size or name. Ask how the method affects the feel of the print and whether the chosen garment is compatible. If the design includes fine detail, ask how small text and thin lines will reproduce. If the shirts will be washed often, ask about care instructions.

It is also worth asking whether the process includes any proof before production. A proof can reveal spacing problems, color shifts, or placement issues before the full order is printed. For film transfers, check how the artwork is arranged and cut. For direct printing, check how pretreatment and fabric texture may affect the image. For screen printing, confirm the color separations and placement marks.

The best match is rarely the method with the most impressive description. It is the method that fits the garment, artwork, quantity, and expected wear. Screen printing rewards repetition. DTG rewards direct detail on suitable fabric. DTF rewards flexibility across garments and designs. Once those strengths are matched to the order, the decision becomes much simpler.

Custom Shirt Printing is at 11150 Glenoaks Blvd, Pacoima, CA 91331, USA, and can be contacted at (323) 406-0702.
