Key Considerations for Placing Digital Signage Displays

Check your location before you buy

Putting a screen on a wall sounds simple. But when that screen is part of a digital signage setup, the environment around it decides whether the display works reliably or becomes a constant headache. Before you order hardware, it pays to walk the space and think through a few practical points.

Power: not just a plug socket

Every display needs power, and a media player needs power too. A single socket might work for a small test, but a permanent installation deserves a dedicated circuit. You want to avoid tripping breakers when the coffee machine or the cleaning crew's vacuum shares the same line. Check how many outlets you have near the mounting spot and whether they are on a circuit that is already heavily loaded. If the display will run 12 or 16 hours a day, consider a surge protector or an uninterruptible power supply for the media player. A sudden power cut can corrupt files or leave you with a blank screen that needs a manual reboot.

Internet connection: wired is better than wireless

Digital signage content changes. A menu board updates prices, a lobby screen rotates announcements, and a retail display swaps promotions. All of that relies on a stable connection between the display's media player and the content management server. Wi-Fi can be convenient, but it introduces variables: signal strength, interference from other devices, and the occasional dropout that leaves a screen stuck on yesterday's content. Whenever possible, run a cable. That means checking whether a network port exists near the display location or whether you can add one. If you must use Wi-Fi, test the signal at the exact spot where the screen will sit, and use a dedicated access point rather than the one in the back office. For a low cost screen setup, a simple Ethernet cable often saves more time than it costs.

Placement: sight lines, glare, and viewing distance

A screen mounted too high strains necks. A screen placed opposite a window washes out in direct sunlight. The ideal height puts the centre of the display at eye level for someone standing or sitting, depending on the audience. For a waiting room, that is roughly 150 cm from the floor for a seated viewer. For a retail shelf end, the screen might sit slightly above the products. Check the ambient light at different times of day. A bright room with large windows may need a higher brightness display or an anti-glare filter. Also consider the viewing distance:

a 55-inch screen viewed from 6 metres away shows text that is too small to read. Use a simple calculator or a rule of thumb: the furthest viewer should be no more than 3.5 times the screen height away.

Mounting and physical support

A television display weighs several kilograms, and a wall mount adds its own weight. The wall structure matters. Drywall alone cannot hold a large screen securely, especially if the building uses metal studs. You need to locate the studs and use the right anchors. For concrete or brick walls, masonry anchors and a drill are required. If the wall cannot support the weight, consider a floor stand or a ceiling mount. Also plan for cable management. Visible wires look unprofessional and can become a tripping hazard. A simple trough behind the mount or a raceway painted to match the wall keeps things tidy. A low cost screen setup can still look clean with a few metres of cable trunking and a bit of planning.

Device compatibility and signal routing

The media player connects to the display through an HDMI input. That seems straightforward, but there are nuances. Some older displays have HDMI ports that do not supply enough power to run a stick-style player. If the player is separate, check that the cable run from the player to the display is within the standard HDMI length limit, about 10 metres for passive cables. Longer runs need an active cable or a signal extender. Also confirm that the display's screen resolution matches what the player outputs. Most modern players handle 1080p or 4K, but a mismatch can cause scaling artefacts or a blank screen. If the player supports Power over HDMI, you might skip a separate power cable for it, but not all displays deliver that feature. Read the specs before you install.

Environmental factors: heat, humidity, and dust

Displays generate heat, and enclosed spaces trap it. A screen recessed into a wall cavity with no airflow will overheat and shorten its lifespan. Kitchens, outdoor covered patios, and industrial floors add humidity, grease, or dust to the equation. Standard consumer televisions are not built for those conditions. If the location is a kitchen, look for a display with a sealed bezel and a fan filter. If the space gets direct sunlight, the display needs a higher brightness rating, often 700 nits or more, to remain readable. For indoor lobby use with controlled conditions, a standard display rated for 250 to 400 nits works fine. The point is, do not assume one display fits all spots.

Testing before finalising the mount

Before you drill holes, set up the screen on a cart or a table at the planned location. Run content for a few hours. Watch for reflections, check that the Wi-Fi signal holds, and confirm that the power socket does not overheat. This trial run catches issues early. It also lets you verify that the media player's remote management works from the network you plan to use. A quick test saves the cost of moving a mounted screen later.

Thinking about maintenance access

A screen mounted flush against a wall looks sleek, but every piece of electronics eventually needs attention. The media player may need a reboot, the HDMI cable might loosen, or the display's menu settings might need adjustment. Leave enough slack in the cables to pull the screen forward without disconnecting everything. A mount with a tilt or a swing arm makes access easier. If the screen is in a high traffic area, consider a lockable mount or a security bracket to prevent theft or tampering.

Checking power, internet, placement, mounting, device compatibility, and the environment before you install is not overthinking. It is the difference between a display that runs quietly for years and one that demands constant attention. A little planning at the beginning keeps the signage reliable and the audience engaged.
