

Botanical gardens usually keep tropical plants in heated glasshouses or other protected indoor spaces during winter. Staff adjust warmth, light, humidity, and watering to suit the plants while watching for pests and signs of stress.

Keeping the cold outside

A tropical collection may include plants from rainforests, warm grasslands, and other habitats, so one temperature does not suit every specimen. Garden staff group plants with similar needs where they can and monitor the conditions in each growing space.

Heating systems help prevent cold damage when outdoor temperatures fall. Staff also watch for cold spots near glass, doors, and vents. A plant beside an entrance, for example, may feel a chilly draft each time someone steps inside.

Some tropical plants spend warm months outdoors and move under cover before cold weather arrives. Large or permanent collections may stay in a glasshouse throughout the year.

Making the most of winter light

Shorter days and cloudy weather can slow growth. Glass lets in available daylight, and some gardens use artificial grow lights where plants need more light than winter provides.

Staff consider each plant before moving it closer to a window or lamp. A sun lover and a plant that grows beneath a forest canopy may need very different levels of light. Leaves pressed against cold glass can also be damaged, even in a heated room.

Balancing water and humidity

Watering changes with the season and the plant. When growth slows, soil may stay wet longer, so staff check it rather than watering every pot on the same schedule. A finger in the soil or a moisture meter can help show when a plant needs a drink.

Humid air is important for many tropical species, but damp conditions can also encourage disease. Gardens may use humidifiers or other systems to add moisture while keeping air moving. Staff look for practical clues, including dry leaf edges, persistently wet soil, and condensation.

Checking plants day by day

Winter care involves close observation as well as equipment. While watering or removing fallen leaves, staff can spot a problem before it spreads through a collection. They may look for:

- Insects on stems and the undersides of leaves
- Yellowing, wilting, or damaged foliage
- Soil that remains unusually wet or dry
- Signs of rot or fungal growth

If pests appear, staff choose a response suited to the plant and the garden. That might mean removing affected material, isolating a plant, or using a suitable pest control method. Clean tools and regular inspection help protect neighboring plants.

Questions about tropical plants in winter

Do all tropical plants need the same temperature?

No. Tropical plants come from different habitats, and their preferred temperatures vary. Gardens plan care around the needs of the species in their collections.

Do gardens water tropical plants less in winter?

Often, but not always. A plant using less water may need fewer drinks, while one growing actively in a warm glasshouse may still need regular watering.

Can visitors see tropical plants during winter?

Many gardens keep public glasshouses open in colder months. Access depends on the garden and its opening arrangements.
